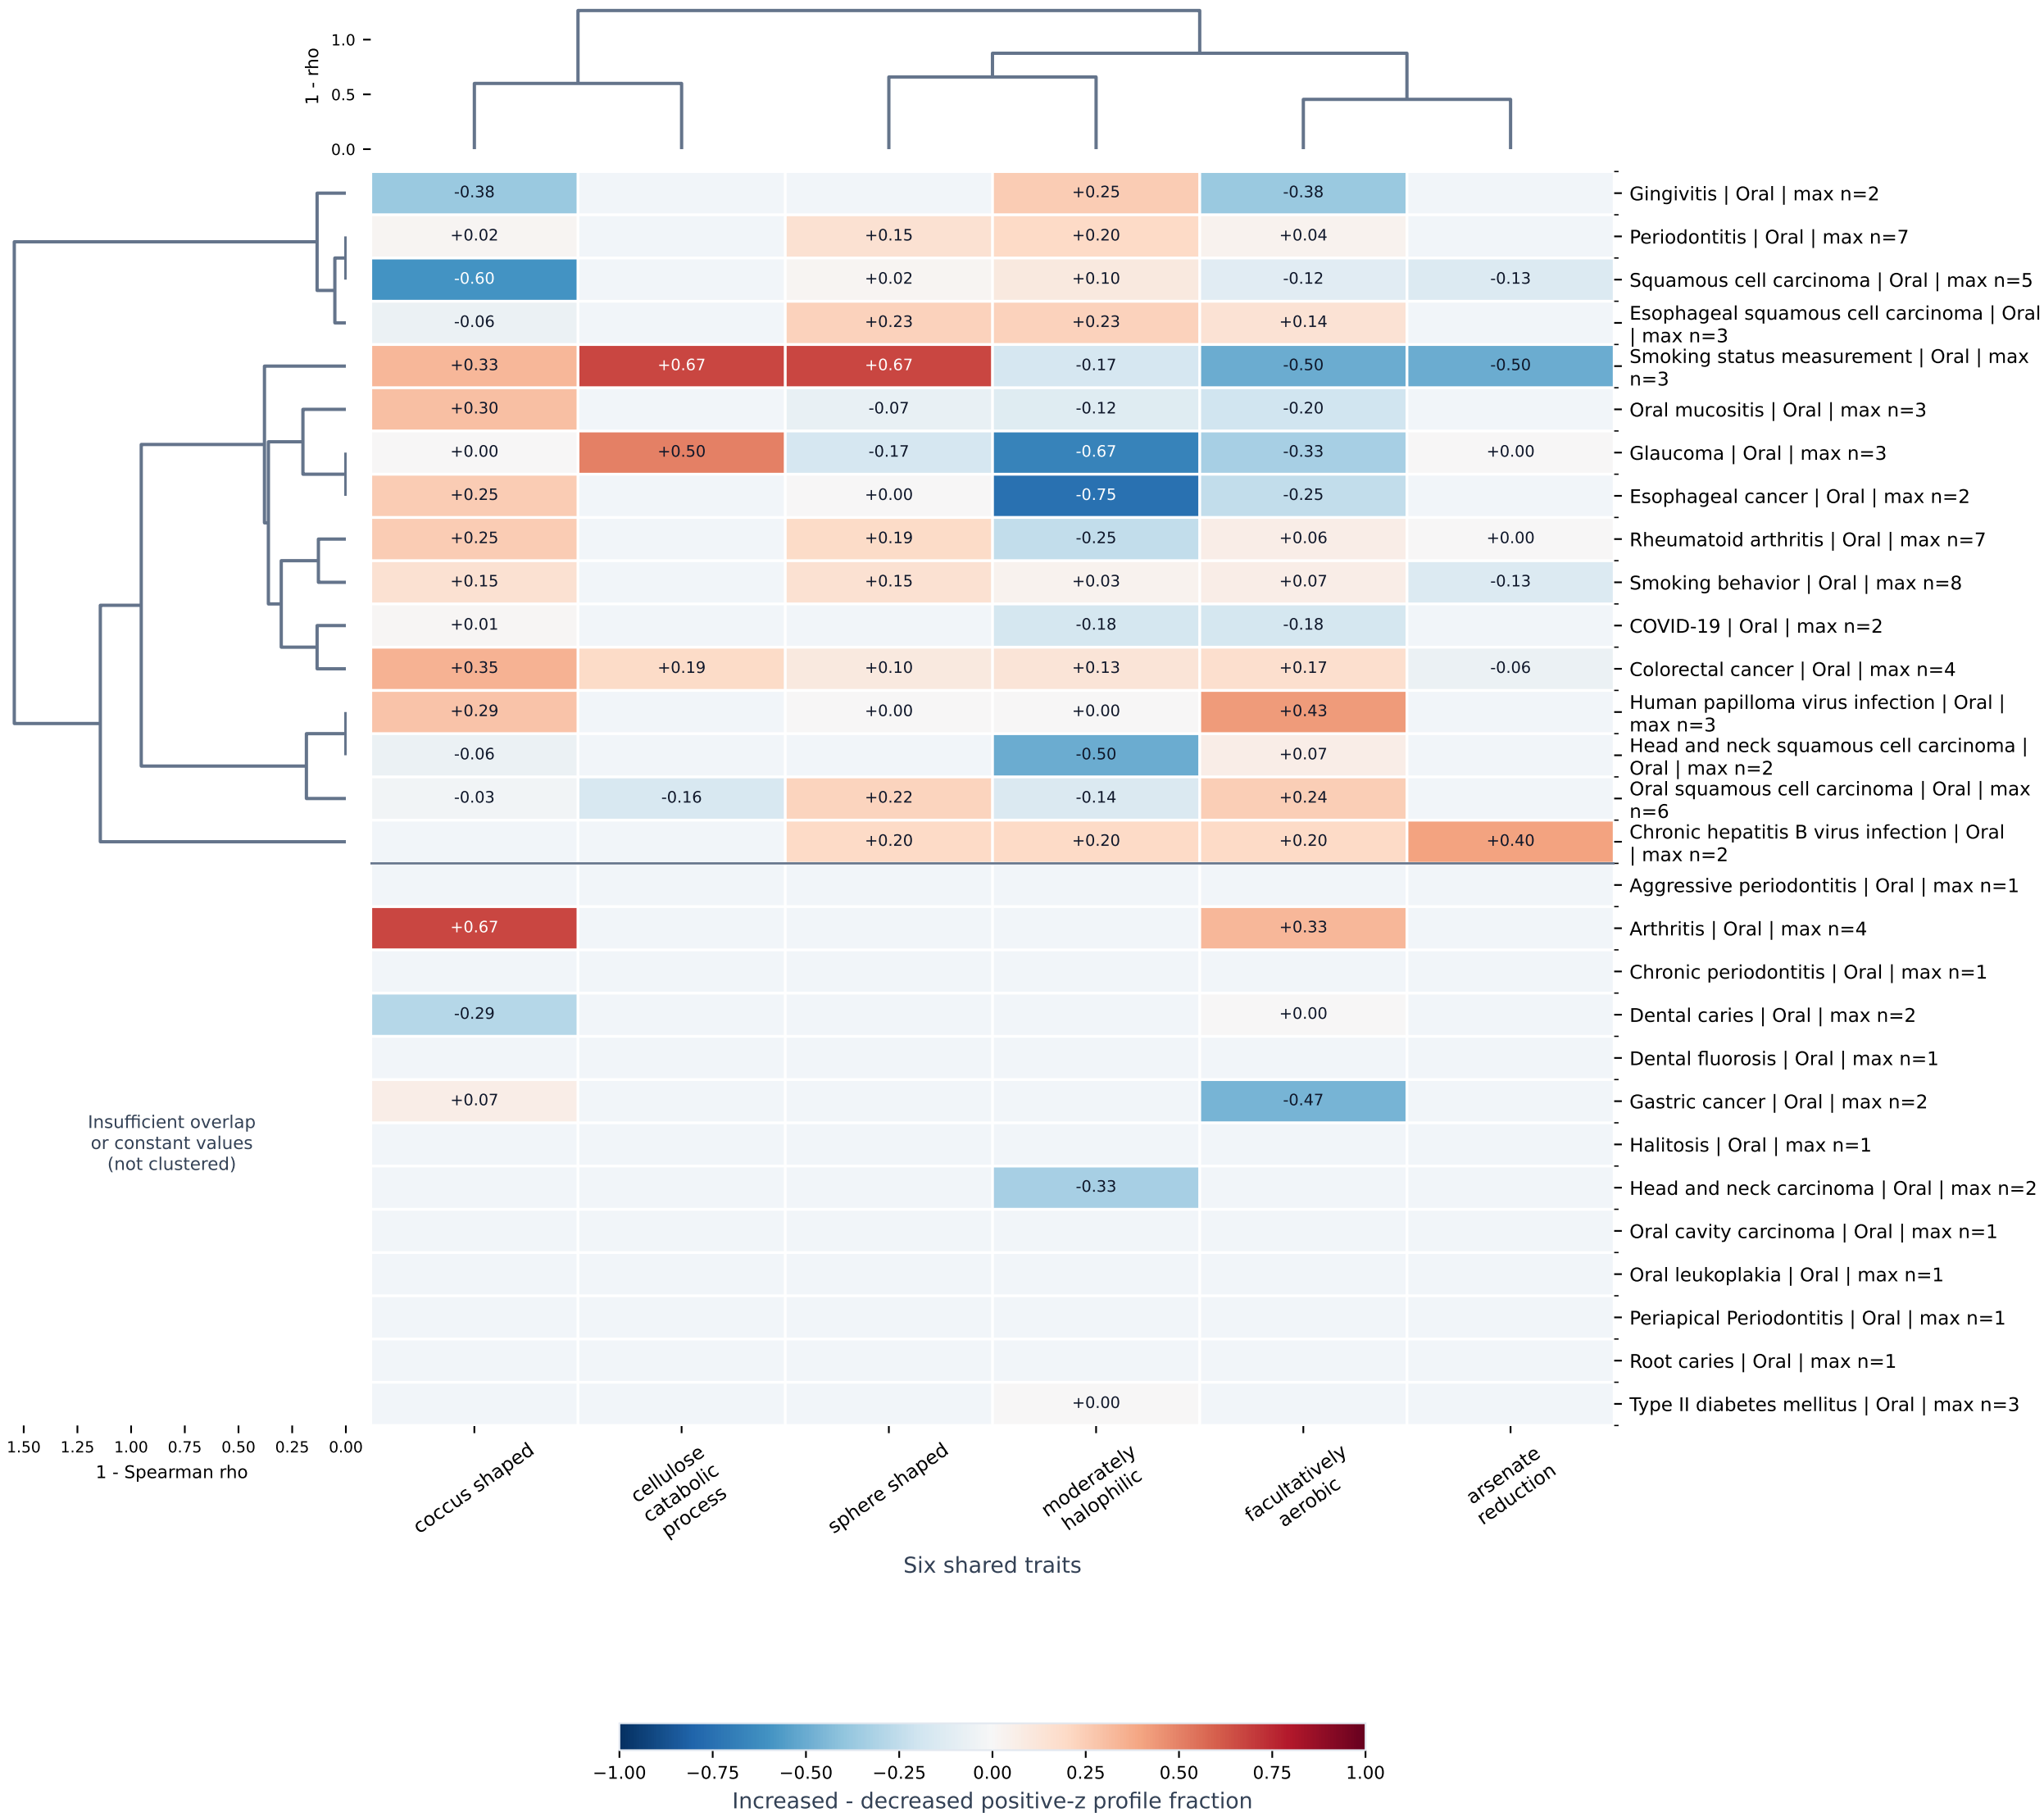
Oral microbiomes and oral diseases: clustered axes


Oral sampling site OR oral disease. Red: increased; blue: decreased positive-z profile fraction. Numbers are increased minus decreased fractions; max n = largest per-trait study count in each row. Dark border: source BH q <= 0.05 (0 oral cells); original 2379-cell family retained. Gray: unavailable or below source support (>=3 positive-z profiles in either direction and >=2 studies), not nonsignificant. Source tests are profile-level diagnostics. Average-linkage clustering on both axes: 1 - Spearman rho, at least 3 shared supported values. Undefined pair distances use 1; vectors with no defined peers remain outside the trees. Clusters are exploratory. Showing 29 of 80 oral rows.
